VOLUME II
LIST OF APPENDICES

APPENDIX A MULADDAH CLIMATE DATA	224
APPENDIX B WELL OPERATIONAL STATUS	227
APPENDIX C FARM AREAS	234
APPENDIX D ELECTRICAL CONDUCTIVITY PER WELL	235
APPENDIX E METER DATABASE.....	270
APPENDIX F MONTHLY ABSTRACTION PER WELL (1994-2000)	274
APPENDIX G SUMMARY OF WELL ABSTRACTION (1994-2000).....	321
APPENDIX H MONTHLY ABSTRACTION PER FARM (1994-2000)	329
APPENDIX I SUMMARY OF CROP SURVEYS (1994-1998).....	358
APPENDIX J CROP DISTRIBUTION PER FARM (%)	369
APPENDIX K SUMMARY OF IRRIGATION METHODS	373
APPENDIX L IRRIGATION METHODS PER FARM	375
APPENDIX M CASE STUDY FARM MAPS	386
APPENDIX N IRRIGATION & PLOT WATER BALANCE- GRASS	403
APPENDIX O IRRIGATION RATES - ALFALFA	443
APPENDIX P SOIL MOISTURE MONITORING RESULTS - GRASS	449
APPENDIX Q SOIL MOISTURE MONITORING RESULTS - ALFALFA.....	457
APPENDIX R CU - SPRINKLERS ON CASE STUDY FARMS.....	474
APPENDIX S COEFFICIENT OF UNIFORMITY - SPRINKLERS	487
APPENDIX T COEFFICIENT OF UNIFORMITY - BUBBLERS	489
APPENDIX U AVERAGE FARM IRRIGATION (ECAV)	491
APPENDIX V TRENDS IN ABSTRACTION AND ECAV	495
APPENDIX W CROP AND GROSS IRRIGATION REQUIREMENTS.....	498
APPENDIX X GROSS IRRIGATION REQUIREMENTS.....	503

APPENDIX Y TOTAL GROSS IRRIGATION REQUIREMENTS.....	521
APPENDIX Z TDR READINGS AND SOIL WATER TENSION	524
APPENDIX AA SME READINGS.....	529
APPENDIX AB SUMMARY OF PLOT WATER BALANCES - GRASS	531
APPENDIX AC PLOT WATER BALANCES - ALFALFA	532
APPENDIX AD DISTRIBUTION OF SPRINKLER FREQUENCY	535
APPENDIX AE BARKA PROFILE MODEL.....	537
APPENDIX AF BARKA PROFILE MODEL RESULTS	545

APPENDIX A
MULADDAH CLIMATE DATA

Mean Monthly ET_o for 1983-94

	Mean	Mean Maximum	Mean Minimum
Jan	3.10	3.37	2.67
Feb	3.84	4.34	3.46
Mar	4.92	5.61	4.22
Apr	6.50	7.25	5.78
May	7.69	8.31	6.72
Jun	7.79	8.27	7.22
Jul	7.18	8.02	6.49
Aug	6.48	6.90	5.74
Sep	6.08	6.62	5.58
Oct	5.21	5.58	4.81
Nov	3.80	4.00	3.43
Dec	3.05	3.17	2.85

Reference Evapotranspiration for Muladdah 1983-94

APPENDIX E
METER DATABASE

APPENDIX E
METER DATABASE

1. Meter Database

A database was developed for storage and querying of data on abstraction and water quality per well. Listed below is an outline of the database and explanation of the method for computation of abstraction and water quality. It is supported with samples of the various forms on which field data was recorded for data entry.

2. Field Activities

2.1. Meter Reading

All operational wells were routinely visited to record meter reading and water electrical conductivity and temperature. The frequency of reading was initially fortnightly on Phase 1 wells from March 1994 to October 1995, and after which all readings were on a monthly basis. Farms were visited in a systematic order, based on proximity from east to west, over the month, with between 5 to 8 farms visited per day dependent on the number of wells per farm. Readings and comments were recorded on the "Meter Reading" form, listing farm, well and meter numbers, meter reading, and water EC and temperature. (Form 1).

2.2. Meter Maintenance

During farm visits for metering reading any operational problems with the water meter were noted and recorded on a 'Meter Fault' form, for follow-up maintenance. The form listed details of date, farm, well, meter and type of fault (Form 2). The farm was subsequently visited to repair or, if necessary, replace the meter. A range of faults were encountered including stone blockages, internal corrosion, malfunction of meter registers and mechanical faults. Meters were disassembled on site to identify the faults and repaired if possible or when not possible replaced. Details of maintenance activities and meter replacements was recorded on a 'Meter Maintenance' form (Form 3). The form listed date, farm, well, meter, type of fault, as well as details of the remedial action(s), and replacement meter including meter readings (existing and new).

2.3. Meter Calibration

All meters were routinely calibrated to verify accuracy of reading. Three calibration methods were employed over the research period, these were:

- Volumetric calibration; on wells with a storage tank, the meter reading was compared with the measured tank volume.
- Comparative calibration; where there was no storage tank, a second calibrated meter was coupled to a discharge point, downstream of the well meter, and readings compared for the two meters.
- Meter Test Bench; from October 1997 onwards meters were taken to the MWR Metering Workshop at Barka, which comprises of meter test bench, electromagnetic meter and calibrated storage tank. Meters were tested for accuracy of reading at minimum (Q_{min}) and maximum (Q_{max}) flows.

The results of the calibration tests were recorded on a 'Meter Calibration' form (Form 4), on which the accuracy was calculated. The minimum acceptable accuracy of reading was plus or minus 2% for helical vane meters and 5% for proportional meters. Meters that fell outside these ranges were adjusted (with the meter calibration adjustment) and re-calibrated. When it proved not possible to attain an acceptable level of accuracy by adjustment the meter was replaced.

3. Metering Database

During the initial stage of the study programme a database was developed for the storage and querying of information on meters and meter readings. The database was developed in Paradox (version 4.0) software with the compilation of tables, forms and scripts for data entry, data validity checks, querying and reporting. The water meter number (an assigned six digit number between 000-001 to 000-500) was the key field in all tables. Listed below is an outline of the database, its structure and the method for computation of abstraction.

3.1. Structure

The database comprises a series of menu and submenus for data entry, querying and reporting as presented in Table 1. The structure provides for data entry functions for addition of new water meters, relocation of existing meters, entry of meter reading and editing of existing reading. Abstraction records were queried for all farms and wells or on an individual farm or well basis, over a specified reporting period. Outputs from these queries could be either print

APPENDIX E METER DATABASE

and/or exported to a Lotus spreadsheet, from which the various tables in the appendices were compiled.

Table 1 Database Menu Structure and Functions

Menu	Submenu	Function
Master	Meter Details	Entry of new meter and recording of meter make, meter number, diameter and type.
	Meter Relocation	Entry of relocation of meters, recorded the date and location of meters.
Data Entry	Enter New Reading	Entry of meter reading, date, water EC and temperature.
	Edit Meter Reading	Edit an existing meter reading, water EC and temperature
Abstraction	Summary for all Farms	Total abstraction for all farms over a specified query period
	Summary for a Farm	Total abstraction for an individual farm over a specified query period.
	All Farms and Wells	Total abstraction for all farms and wells over a specified query period.
	Select a Farm	Total abstraction for an individual farm and well(s) over a specified query period.
	Select a Well	Total abstraction for an individual well over a specified query period.

3.1.1. Validity Checks

The database incorporated a number of validity checks to prevent the entry of invalid data, these included:

- Date; date entries could not post date current date nor precede an existing date entered for a meter reading.
- Meter Reading; a meter reading could not be less than an existing meter reading or exceed more than 8 digits (999,999.99)
- Meter Number; a meter number could not be entered on a well (relocation) if that meter existed on another well.

The validity checks formed the primary quality control of data entry. All records were further evaluated post data entry for erroneous records.

3.2. Computation of Abstraction

A methodology was developed within the database for the computation of abstraction for the specified query period. For the purposes of comparison of abstraction between wells and farms, and over time, it was necessary to develop a method of calculating abstraction over standard query periods, typically a calendar month and year. Meters were read through the month, and often the same meter on different days of each month, they were also relocated or replaced. Therefore abstraction records were stored on a farm, well and meter basis, along with the total abstraction and rate (m^3d^{-1}) between the reading dates (start day and end day). The calculation of abstraction was based on the well, and sum of wells for a farm. Individual well abstraction is therefore the sum of the daily rates (m^3d^{-1}) pro rata over the query period. The records for the computation of abstraction were queried on a monthly basis for wells and farms, and the results presented in Appendices F, G, and H.

APPENDIX W

**CALCULATION OF CROP AND GROSS IRRIGATION
REQUIREMENTS**

Figure 1 Reference ETo from Muladdah

Net cropped area (NA) was a proportion of the gross plot area, corrected to account for uncropped areas within the plot due to headlands, tracks, irrigation channels and bunds. For grass plots NA is 95% of the plot area. For all other crops (tree, fodder and vegetables) it is 80% of the plot area.

Monthly crop coefficient (Kc) values (Figure 2) were derived from FAO Irrigation and Drainage publication no. 24 (FAO, 1984).

Figure 2 Crop Coefficients

Leaching fraction is calculated from the leaching requirements (LR), using the following equation:

Equation 2

$$LR = 1 / (1-Lf)$$

The LR is the minimum amount of irrigation water drained through the root zone to control soil salinity. Soil types on the study farms ranged from sandy loam to sandy gravel and all have high permeability. Based on the recommendations in FAO Irrigation and Drainage Paper No. 24 (FAO, 1984) for permeable soils with high irrigation frequency the LR was calculated using the following equation:

Equation 3

$$Lf = ECw / (2 \times Max\ ECe)$$

where:

- Ecw = electrical conductivity of irrigation water (μScm^{-1})
- ECe = maximum tolerable electrical conductivity of the soil saturation extract for a given crop (μScm^{-1})

Table 1 presents the maximum ECe values adopted for the calculation of Lf, derived from a review of international and local salinity research (Mott, 1991) and FAO Irrigation and Drainage Paper No. 48 (FAO, 1991). It also lists the maximum ECw values based on the relationship ECe is approximately 1.5 times ECw.

Table 1 Max ECe and ECw Values

Crop	ECe (μScm^{-1})	ECw (μScm^{-1})
Alfalfa	16,000	10,666
Banana	8,000	5,333
Coconut	32,000	21,333
Datepalm	32,000	21,333
Grasses	18,000	12,000
Limes	8,000	5,333
Mango	8,000	5,333
Mixed Trees Plots	8,000	5,333
Other Trees Sp.	8,000	5,333

Vegetables	10,000	6,666
------------	--------	-------

Crop growth and production is sensitive to soil and water salinity. While the level of sensitivity varies between crops, above a threshold level salinity increases and productivity declines and ultimately ceases above a critical level. The relationship between crop yield and soil water salinity is described as:

Equation 4

$$Y_r = 100 - b (EC_e - a)$$

where:

Y_r = relative yield (%) under saline compared to non saline threshold salinity conditions

a = threshold salinity (above which yield declines)

b = percentage decrement value per unit increase of salinity in excess of a

As soil water salinity increases, (Maas and Hoffman, 1977) relative yield progressively declines from 100% at threshold EC_e to 0% at maximum EC_e . At maximum EC_e the leaching fraction is 0.33. Based on Equation 2, leaching requirements are 1.5 and therefore this was established as the upper limit for leaching requirement for calculation of GIR.

Table 3 presents the irrigation efficiency (EU) values assumed in the calculation of GIR. These assumed values are based on limited research in Oman and values traditionally adopted for system efficiencies.

Table 3 Irrigation Efficiency Values

Method	EU %
Surface Lined	60
Surface Unlined	50
Drip/Bubbler	90
Sprinkler/Spray	70

GIR values were calculated on a monthly basis using an Excel spreadsheet and a Paradox database. These values form the basis for the investigation of the relationship between

irrigation water salinity, abstraction and irrigation demand presented in the following section. The full result of GIR calculations per farm are listed in Appendix X.

APPENDIX X

**GROSS IRRIGATION REQUIREMENTS
PER FARM**

BARKA PROFILE MODEL

APPENDIX AE

BARKA GROUNDWATER PROFILE MODEL

This appendix provides an overview of the Barka Goundwater Profile Model developed in 1994-95, by Mr. Richard Lakey (Lakey, 1996). The purpose of the model is to provide a methodology for the assessment of the impact of land use and management options on groundwater in the southern Batinah. Mr. Lakey kindly consented to the use of the model for the evaluation of management options presented in Chapter Seven (Volume 1) of this study. Appendix AF lists the model results in tabular form.

The model is the first stage in the development of a three dimensional areal flow model (MODFLOW) for the southern Batinah, to include Wadis Taww, Ajal (a recently defined sub-unit of Taww and Ma'awil), and Ma'awil and the adjacent catchments to the north of Wadis Bani Kharus and Fara (MWR, 1996c). The development of this larger sub-regional model was initiated in the mid-1990s, however it yet to be commissioned due to other priority work.

The Barka Profile model provides the best available tool for the assessment of spatial and temporal changes in groundwater conditions within the study area. As described below, the model is a representative "slice" of the aquifer and has been calibrated against monitoring wells within the area over the period 1977-96. Listed below is a description of the model, its calibration and sensitivity analysis. In general the model is reported to be quite robust and can accommodate large flux changes without becoming unstable (Lakey, 1996).

Model Description

The model is based on a comprehensive study of the hydrogeological features of the southern Batinah (MWR, 1995c), utilizing information and data from drilling and geophysical programmes, hydraulic testing , chemical sampling and long-term monitoring records for rainfall, wadi flow and groundwater level. The selected profile is located to provide a representative 'slice' of the hydrogeological and agricultural characteristics of the area, as well as to take best advantage of calibration data from drilling, testing and well monitoring records.

The development of the model included the evaluation of water flow and storage characteristics for three layers, based on well lithology and pumping test results. It also integrates data from the National Well Inventory Programme for all farms located within the slice. Water demand is based on the combined net water demand within each model cell. The net demand is defined as the net loss of water to evaporation and evapotranspiration, from both irrigated and natural vegetation.

The model slice is located approximately in the centre of Wadi Ma'awil and runs inland perpendicular to the coast across the alluvial plain and into the mountainous upper catchment, as shown in Figure 1.

The model domain is based on cells of 1,250 m side length transecting the Wadi Ma'awil catchment, from the sea to the upper catchment. It comprises three layers according to the primary hydrostratigraphic units, these are:

Layer 1: Sub Recent and Recent alluvium; unconfined

Layer 2: Ancient alluvium; semi confined

Layer 3: Various bedrock units; ranging from unconfined to confined

Figure 2 illustrates the hydrogeological cross-section of the profile, location of the cells (rows 10-35) and monitoring wells. The model was calibrated on the historical records of groundwater levels from eight monitored wells, located within the slice. Four of these wells (JT-72, BM-1, RE-4 and RE-3) were selected to present the response and trends (current and predicted) in groundwater levels, as discussed in Chapter Seven.

It should be noted that for the purposes of this study the cells of primary interest in terms of evaluation of responses to management options, are those located on the lower coastal plain, within the study area, these are rows 12-19. All four of the above monitoring wells are located within these cells.

All extraction on the coastal plain is from Layer 1. The primary role of both Layers 2 and 3 is to transmit recharge to Layer 1. Therefore the following sections refer primarily to Layer 1.

The following description of the model calibration and sensitivity analysis was provided by the model developer, Mr. Richard Lakey, and is based on a previously published description of the model (Lakey, 1996).

Calibration

The history of the area indicates that a steady increase in development has occurred since the early 1960s. There is no water level data available for that time, nor are any records of the change in extraction over time available. It is highly probable that this flow system has never been in steady state since the early 1960s.

The longer hydrograph records clearly show a steady decline from the early 1970s when monitoring commenced. Early simulations showed that the flow system is very sensitive to extraction, and comparatively insensitive to direct recharge to Layer 1. This is primarily due to the relative magnitude of these fluxes and the size of groundwater storage.

It is not therefore realistic to attempt to define the hydraulic conductivity distribution using the conventional steady state simulation approach, based upon an estimated average extraction, average recharge, and assumed hydraulic head distribution. Consequently a different approach was adopted.

The first stage of the calibration involved adjusting the pre-1981 extraction (rows 12 to 15), to achieve the observed hydraulic gradient and hydrograph response using a realistic range of K and S values, based upon the hydraulic data review presented in Lakey (1996).

The first stage of calibration was achieved when:

- The correct hydraulic gradient from RE-3 to JT-72 was established and maintained;
- The simulated response matched the observed response of the observation wells up to 1981 in the northern area (north of ADG-17) without disturbing the water table further south;

- Bedrock seepage did not inflate the water table, nor cause water table decline; i.e. seepage could be transported by the alluvium without mounding;
- Layers 2 and 3 heads and gradients were stable and acceptable;
- There was no significant change in storage during the simulation (Dec 1976 to Dec 1992).
- An acceptable hydraulic conductivity distribution was obtained.

The second stage of calibration involved the progressively increasing extraction from rows 16 to 19 from 1982 to 1992 until the observed hydrograph response in all observation wells was simulated correctly. Progressive development in rows 16 to 19 was sufficient to produce the additional drawdown observed in the traditional farming area over this period. Using this method, calibrations were achieved for two hydraulic conductivity distributions (low (40 md^{-1}) and high (60 md^{-1})) within rows 12 to 19. Observation well calibrations are shown in Figures 3 to 5. The plots for the low hydraulic conductivity were almost identical. One of the compromises involved in using a finite difference model is that cell nodes and observation well locations do not always coincide. For example well JT-72 is located mid way between rows 12 and 13, if the well is calibrated against row 12, drawdown is lower than the observed level, whereas row 13 results in greater than observed drawdown.

Sensitivity Analysis

The sensitivity of the model to hydraulic conductivity, specific yield, direct recharge and extraction was tested systematically varying each parameter and observing the response.

Layer 1 is predictably highly sensitive to extraction, the dominant flux. The extraction distribution has been derived from the NWIP and adjusted during calibration for progressive development pre-inventory. Since the base data have been obtained by detailed field survey it is considered the best available.

As shown in Figures 6 and 7 the sensitivity of the model to hydraulic conductivity increases with increasing extraction north of the Batinah highway (greater than row

16), and that it is relatively insensitive to hydraulic conductivity south of the highway in the more highly transmissive thicker aquifer sequence.

The sensitivity to reducing specific yield from 0.2 to 0.05 in the main production areas north (rows 12-15) and south (16-19) of the highway is presented in Figure 8. It shows that sensitivity increases with increasing extraction with no significant effect evident until the post 1981 increase in pumping. The model is more sensitive to specific yield in the area south of the highway, due to the greater reliance on stored water compared to the near coastal area where yield is buffered by saline intrusion. The model was calibrated with mid range specific yields of 0.20 and 0.15 for the high and low hydraulic conductivity calibrations respectively.

Summary of Flow System Response to Development

Water goes into storage in all layers during wet periods and is released during dry periods, but as extraction increases recharge becomes inadequate and the water balance is increasingly reliant on storage reduction and saline intrusion. Seepage inflows from Layers 2 and 3 remain relatively constant because the controlling gradients are relatively constant. Seepage continues through both wet and dry stress periods. However, there is a steady increase in the rate of saline intrusion as water tables drop along the coast.
